National Toxicology Program; Availability of Technical Report on Toxicology and Carcinogenesis Studies of Phenolphthalein

The HHS' National Toxicology Program announces the availability of the NTP Technical Report on the toxicology and carcinogenesis studies of phenolphthalein which is used as a laboratory reagent and acid-base indicator and in over-the-counter laxative preparations. The results of these studies were previously released in draft form prior to a public peer review in December, 1995.

Toxicology and carcinogenicity studies were conducted by administering phenolphthalein to groups of 50 F344/N rats for 2 years and to B6C3F₁ mice at exposures of 0, 3000, 6000 or 12,000 ppm in the feed for 2 years (equivalent to average daily doses of approximately 300, 600 or 1200 mg phenolphthalein/kg body weight to

males and 400, 800 or 1000 mg/kg to females).

Under the conditions of these 2-year feed studies, there was clear evidence of carcinogenic activity¹ of phenolphthalein in male F344/N rats based on markedly increased incidences of benign pheochromocytomas of the adrenal medulla and of renal tubule adenomas and adenomas or carcinomas (combined). There was some evidence of carcinogenic activity of phenolphthalein in female F344/N rats based on the increased incidences of benign pheochromocytomas of the adrenal medulla in the 12,000 ppm group and of benign or malignant pheochromocytomas (combined) in the 12,000 and 25,000 ppm groups. There was clear evidence of carcinogenic activity of phenolphthalein in male B6C3F₁ mice based on increased incidences of histiocytic sarcomas and of malignant lymphomas of thymic origin. There was clear evidence of carcinogenic activity of phenolphthalein in female B6C3F₁ mice based on increased incidences of histiocytic sarcomas, malignant lymphomas of all types, lymphomas of thymic origin, and benign sex-cord stromal tumors of the ovary.

Exposure of rats to phenolphthalein in feed for 2 years resulted in increased incidences of focal hyperplasia of the adrenal medulla in males and in increased incidences and/or severity of nephropathy of the kidney in males and females. Exposure of mice to phenolphthalein in feed for 2 years resulted in increased incidences of atypical hyperplasia of the thymus in males and females, degeneration of the germinal epithelium of the testis in males, and ovarian hyperplasia in females.

Exposure of mice to phenolphthalein in feed for 2 years resulted in decreased incidences of hepatocellular neoplasms and nonneoplastic lesions in males and females.

Questions or comments about the Technical Report should be directed to Central Data Management at P.O. Box 12233, Research Triangle Park, NC 27709-2233.

Copies of *Toxicology and Carcinogenesis Studies of Phenolphthalein* (CAS No. 77-09-8) (TR-465) are available from Central Data

¹ The NTP uses five categories of evidence of carcinogenic activity observed in each animal study: two categories for positive results ("clear evidence" and "some evidence"), one category for uncertain findings ("equivocal evidence"), one category for no observable effect ("no evidence"), and one category for studies that cannot be evaluated because of major flaws ("inadequate study").
