

High Sensitivity Phage Display Protein Detection Method

Carl R. Merrill (NIMH) DHHS
Reference No. E-185-98/0 filed 14 Apr 1999.

This new technology extends the range of protein detection appreciably under the absolute limit of 0.01ng for the Silver stain method. In an average protein molecule this amounts to 20 million molecules. The average cellular concentration of protein is 5000 molecules, so that an amplification system is needed to detect protein on that level. In this method, phage that display specific ligands or antibodies provide such an amplification system and therefore allow for detection. In addition, a particular phage expressing a known binding protein may be used to identify a specific protein and aid in the purification of that specific protein. The identification ability has both diagnostic and therapeutic potential.

The key novel feature of this technology in the market place would be its high sensitivity and the numerous benefits associated with it. It opens up whole new areas of analysis, such as on the cellular level, allowing for looking at protein variations within a single cell. Theoretically, as little as one protein molecule could be detectable.

The potential market for this invention would be in several distinct areas: Research—incorporation into kits to perform complete assays; Purification—aiding in the manufacturing process; Diagnostic—detection of variations of a specific protein within a cell; Therapeutic—identification of specific drug targets through the ability to bind to receptor sites.
